

Function of grounding flat copper wire in distribution box

Overview

Grounding is a mechanism to protect distribution equipment and people under normal operating conditions, abnormal operational (overcurrent and overvoltage) responses, and hazardous conditions such as shocks. This helps to reduce the potential difference that exists between conductive parts and the earth. Equipment Protection: Grounding protects substation. Using bare copper wire combines the best features for performance and longevity in this non-current-carrying application. Each DISTRIBUTION BOX and controller must be grounded. 26 mm² (10 AWG) ground wire must be used, and in all other markets a 6 mm² must be used. Earthing involves establishing a conductive path from the electrical system to the Earth's. A ground wire, also known as a grounding wire or ground conductor, as the name implies, is an electrical wire connected from the transformer and main panel (or distribution board) to the ground rod or earthing plate via an earthing lead buried in the ground or Earth. It is connected to all metallic.
