

# Is the beam splitter s output evenly distributed across all channels

## Overview

The beam splitter uses a micro-prism or a diffraction grating to divide the input signal based on wavelength, resulting in a uniform output signal across all the output channels. Electric elds  $E_1$  and  $E_2$  enter input ports 1 and 2, respectively. Note that  $jT$   $j_2$  is the transmitted intensity. It is a crucial part of many optical experimental and measurement systems, such as interferometers, also finding widespread application in fibre optic telecommunications. If we neglect the three-dimensional character of the electromagnetic fields and focus on one-dimensional propagation only, we can regard a beam splitter simply as a dielectric plate, possibly consisting of several y consisting of several layers ropagation along. Beamsplitters are optical components used to split incident light at a designated ratio into two separate beams. This division allows for the simultaneous analysis or utilization of the light's properties along two separate paths.

In its most common form, a cube, a beam splitter is made from two triangular glass prisms which are glued together at their base using polyester, epoxy, or urethane-based adhesives. (Before these synthetic resins, natural ones were used, e.g. Canada balsam.) The thickness of the resin layer is adjusted such that (for a certain wavelength) half of the light incident through one "port" (i.e., face of the cube) is reflected and th
