

Principles of Optical Transceivers and Beam Splitters

Overview

A beam splitter or beamsplitter is an optical device that splits a beam of light into a transmitted and a reflected beam. It is a crucial part of many optical experimental and measurement systems, such as interferometers, also finding widespread application in fibre optic telecommunications. DesignsIn its most common form, a cube, a beam splitter is made from two triangular glass which are glued together at their base using polyester,, or urethane-based adhesives. (Before these synthetic. Beam splitters are sometimes used to recombine beams of light, as in a. In this case there are two incoming beams, and potentially two outgoing beams. But the amplitudes. For beam splitters with two incoming beams, using a classical, lossless beam splitter with E_a and E_b each incident at one of the inputs, the two output fields E_c and E_d are linearly related to the inputs thro.
